Index	95

OpenSCM two layer model contains implementations of the two layer radiative forcing driven models by [Held et al.](#), [Geoffroy et al.](#) and [Bloch-Johnson et al.](#)

OpenSCM Two Layer Model was designed to provide a clean, modularised, extensible interface for one of the most commonly used simple climate models. It was used in [Phase 1 of the Reduced Complexity Model Intercomparison Project](#) as a point of comparison for the other participating models.

The [FaIR model](#) implements a mathematically equivalent model (under certain assumptions) but does not provide as clear a conversion between the two-layer model and the two-timescale response as is provided here. We hope that this implementation could interface with other simple climate models like FaIR to allow simpler exploration of the combined behaviour of interacting climate components with minimal coupling headaches.

As implemented here, the “OpenSCM Two Layer Model” interface is target at researchers and as an education tool. Users from other fields are of course encouraged to use it if they find it helpful.

OpenSCM two layer model is free software under a BSD 3-Clause License, see [LICENSE](#).

If you have any issues or would like to discuss a feature request, please raise them in the [OpenSCM Two Layer Model issue tracker](#). If your issue is a feature request or a bug, please use the templates available, otherwise, simply open a normal issue.

INSTALLATION

OpenSCM two layer model has only two dependencies:

- scmdata>=0.9
- tqdm

OpenSCM two layer model can be installed with pip

```
pip install openscm-twolayermodel
```

If you also want to run the example notebooks install additional dependencies using

```
pip install "openscm-twolayermodel[notebooks]"
```

Coming soon OpenSCM two layer model can also be installed with conda

```
conda install -c conda-forge openscm-twolayermodel
```

We do not ship our tests with the packages. If you wish to run the tests, you must install from source (or download the tests separately and run them on your installation).

1.1 Installing from source

To install from source, simply clone the repository and then install it using pip e.g. `pip install ".[dev]"`. Having done this, the tests can be run with `pytest tests` or using the `Makefile` (`make test` will run only the code tests, `make checks` will run the code tests and all other tests e.g. linting, notebooks, documentation).

For more details, see the *development section of the docs*.

Here we provide examples of OpenSCM two layer model's behaviour and usage. The source code of these usage examples is available in the folder `docs/source/usage` of the [GitHub](#) repository.

2.1 Basic demos

2.1.1 Getting Started

This notebook demonstrates the OpenSCM Two Layer Model repository's basic functionality.

We start with imports, their need will become clearer throughout the notebook.

```
[1]: import inspect

import numpy as np
from openscm_units import unit_registry
from scmdata import ScmRun

import openscm_twolayermodel
from openscm_twolayermodel import ImpulseResponseModel, TwoLayerModel
from openscm_twolayermodel.base import Model

/home/docs/checkouts/readthedocs.org/user_builds/openscm-two-layer-model/envs/latest/lib/
→python3.7/site-packages/openscm_twolayermodel/base.py:10: TqdmExperimentalWarning:
→Using `tqdm.autonotebook.tqdm` in notebook mode. Use `tqdm.tqdm` instead to force
→console mode (e.g. in jupyter console)
    import tqdm.autonotebook as tqdman
```

As with most Python packages, the version of `openscm_twolayermodel` being used can always be checked as shown below. This is very helpful for debugging.

```
[2]: # NBVAL_IGNORE_OUTPUT
openscm_twolayermodel.__version__
[2]: '0.2.3+2.gec212a2'
```

OpenSCM Two Layer Model has two key classes: `ImpulseResponseModel` and `TwoLayerModel`. These are implementations of the two major variants of the two-layer model found in the literature. We can see that they both have a common base class using the `inspect` package.

```
[3]: inspect.getmro(ImpulseResponseModel)
```

```
[3]: (openscm_twolayermodel.impulse_response_model.ImpulseResponseModel,
      openscm_twolayermodel.base.TwoLayerVariant,
      openscm_twolayermodel.base.Model,
      abc.ABC,
      object)
```

```
[4]: inspect.getmro(TwoLayerModel)
```

```
[4]: (openscm_twolayermodel.two_layer_model.TwoLayerModel,
      openscm_twolayermodel.base.TwoLayerVariant,
      openscm_twolayermodel.base.Model,
      abc.ABC,
      object)
```

These classes can both be used in the same way. We demonstrate the most basic usage here, more comprehensive usage is demonstrated in other notebooks.

The first thing we need is our effective radiative forcing driver. This should be an `ScmRun <<https://scmdata.readthedocs.io/en/latest/data.html#the-scmrun-class>>`__ instance.

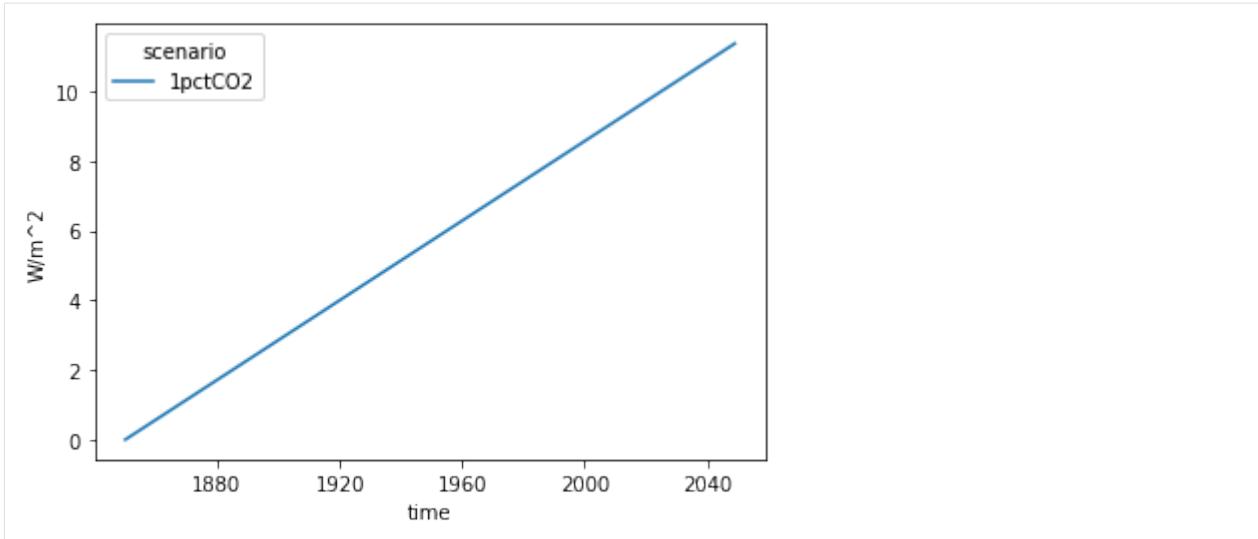

```
[5]: run_length = 200
```

```
driver = ScmRun(
    data=np.arange(run_length) * 4 / 70,
    index=1850 + np.arange(run_length),
    columns={
        "unit": "W/m^2",
        "model": "idealised",
        "scenario": "1pctCO2",
        "region": "World",
        "variable": "Effective Radiative Forcing",
    },
)
driver
```

```
[5]: <scmdata.ScmRun (timeseries: 1, timepoints: 200)>
Time:
    Start: 1850-01-01T00:00:00
    End: 2049-01-01T00:00:00
Meta:
            model region scenario      unit                  variable
    0  idealised   World   1pctCO2  W/m^2  Effective Radiative Forcing
```

```
[6]: # NBVAL_IGNORE_OUTPUT
driver.lineplot()
```

```
[6]: <AxesSubplot:xlabel='time', ylabel='W/m^2'>
```

Then we can initialise instances of our models and run them.

```
[7]: # NBVAL_IGNORE_OUTPUT
two_layer = TwoLayerModel(lambda0=4 / 3 * unit_registry("W/m^2/delta_degC"))
res_two_layer = two_layer.run_scenarios(driver)

impulse_response = ImpulseResponseModel(d1=10 * unit_registry("yr"))
res_impulse_response = impulse_response.run_scenarios(driver)

res = res_two_layer.append(res_impulse_response)
res.head()

scenarios: 0it [00:00, ?it/s]
scenarios: 0it [00:00, ?it/s]

```

[5 rows x 200 columns]

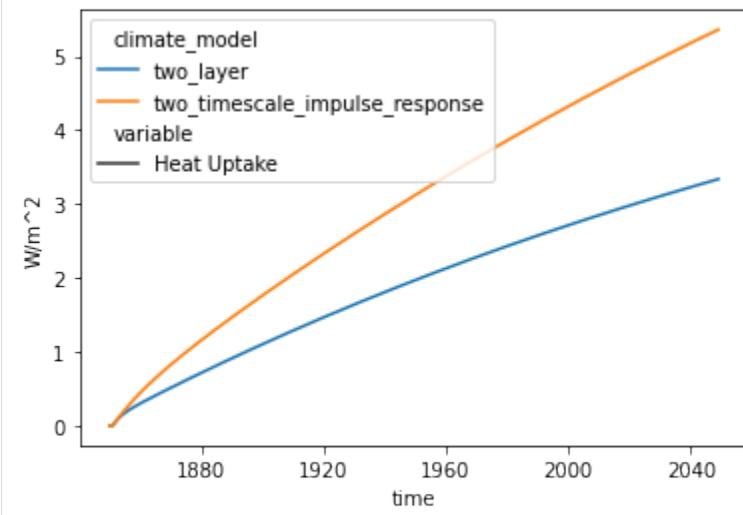

Now we can plot our outputs and compare (of course, we can make these two models the same if we're clever about how we set the parameters, see the impulse response equivalence notebook).

```
[8]: # NBVAL_IGNORE_OUTPUT
res.filter(variable="Surface Temperature*").lineplot(
    hue="climate_model", style="variable"
)
<AxesSubplot:xlabel='time', ylabel='delta_degC'>
```

```
[9]: # NBVAL_IGNORE_OUTPUT
res.filter(variable="Heat*").lineplot(hue="climate_model", style="variable")
```

```
[9]: <AxesSubplot:xlabel='time', ylabel='W/m^2'>
```

2.1.2 Running scenarios

Here we show how multiple scenarios can be run using the OpenSCM Two Layer Model package.

```
[1]: # NBVAL_IGNORE_OUTPUT
import os.path

import numpy as np
import pandas as pd
from openscm_units import unit_registry as ur
import tqdm.autonotebook as tqdman
from scmda import ScmRun, run_append
```

(continues on next page)

(continued from previous page)

```
from openscm_twolayermodel import TwoLayerModel

import matplotlib.pyplot as plt

/home/docs/checkouts/readthedocs.org/user_builds/openscm-two-layer-model/envs/latest/lib/
  ↪python3.7/site-packages/ipykernel_launcher.py:7: TqdmExperimentalWarning: Using `tqdm.
  ↪autonotebook.tqdm` in notebook mode. Use `tqdm.tqdm` instead to force console mode (e.
  ↪g. in jupyter console)
    import sys
```

For this we use RCMIP effective radiative forcing data.

```
[2]: DATA_PATH = os.path.join(
    "...",
    "...",
    "...",
    "tests",
    "test-data",
    "rcmip-radiative-forcing-annual-means-v4-0-0.csv",
)
DATA_PATH
[2]: '/.../.../tests/test-data/rcmip-radiative-forcing-annual-means-v4-0-0.csv'
```

```
[3]: # NBVAL_IGNORE_OUTPUT
scenarios = ScmRun(DATA_PATH, lowercase_cols=True).filter(
    scenario="historical", keep=False
)
scenarios

[3]: <scmdata.ScmRun (timeseries: 480, timepoints: 751)>

2.2 More detail

2.2.1 Impulse response equivalence

In this notebook we explore the equivalence between the two-layer model and a two-timescale impulse response approach.

Background

Following [Geoffroy et al., 2013, Part 2](#), with notation altered to match our implementation, the two-layer model with efficacy (ϵ) and state-dependent climate feedback can be written as

$$C \frac{dT}{dt} = F - (\lambda_0 - aT)T - \epsilon\eta(T - T_D) \quad (2.1)$$

$$C_D \frac{dT_D}{dt} = \eta(T - T_D) \quad (2.2)$$

If the state-dependent feedback factor, a , is non-zero, the two-layer model and impulse response approaches are not equivalent. However, if $a = 0$, they become the same.

Hereafter we assume $a = 0$, however this assumption should not be forgotten. In the case $a = 0$, the two-layer model can be written (adding an ϵ for the deep-ocean equation too for simplicity later).

$$C \frac{dT}{dt} = F - \lambda_0 T - \epsilon\eta(T - T_D) \quad (2.3)$$

$$\epsilon C_D \frac{dT_D}{dt} = \epsilon\eta(T - T_D) \quad (2.4)$$

In matrix notation we have

$$\frac{d\mathbf{X}}{dt} = \mathbf{AX} + \mathbf{B} \quad (2.5)$$

where $\mathbf{X} = \begin{pmatrix} T \\ T_D \end{pmatrix}$, $\mathbf{A} = \begin{bmatrix} -\frac{\lambda_0 + \epsilon\eta}{C} & \frac{\epsilon\eta}{C} \\ \frac{\epsilon\eta}{\epsilon C_D} & -\frac{\epsilon\eta}{\epsilon C_D} \end{bmatrix}$ and $\mathbf{B} = \begin{pmatrix} F \\ 0 \end{pmatrix}$.

As shown in [Geoffroy et al., 2013, Part 1](#), \mathbf{A} can be diagonalised i.e. written in the form $\mathbf{A} = \Phi \mathbf{D} \Phi^{-1}$, where \mathbf{D} is a diagonal matrix. Applying the solution given in [Geoffroy et al., 2013, Part 1](#) to our impulse response notation, we have

$$\mathbf{D} = \begin{bmatrix} -\frac{1}{\tau_1} & 0 \\ 0 & -\frac{1}{\tau_2} \end{bmatrix} \quad (2.6)$$

and

$$\Phi = \begin{bmatrix} 1 & 1 \\ \phi_1 & \phi_2 \end{bmatrix} \quad (2.7)$$

where

$$\tau_1 = \frac{CC_D}{2\lambda_0\eta}(b - \sqrt{\delta}) \quad (2.8)$$

$$\tau_2 = \frac{CC_D}{2\lambda_0\eta}(b + \sqrt{\delta}) \quad (2.9)$$

$$\phi_1 = \frac{C}{2\epsilon\eta}(b^* - \sqrt{\delta}) \quad (2.10)$$

$$\phi_2 = \frac{C}{2\epsilon\eta}(b^* + \sqrt{\delta}) \quad (2.11)$$

$$b = \frac{\lambda_0 + \epsilon\eta}{C} + \frac{\eta}{C_D} \quad (2.12)$$

$$b^* = \frac{\lambda_0 + \epsilon\eta}{C} - \frac{\eta}{C_D} \quad (2.13)$$

$$\delta = b^2 - 4\frac{\lambda_0\eta}{CC_D} \quad (2.14)$$

Given this, we can re-write the system as

$$\frac{d\mathbf{X}}{dt} = \Phi\mathbf{D}\Phi^{-1}\mathbf{X} + \mathbf{B} \quad (2.15)$$

$$\Phi^{-1}\frac{d\mathbf{X}}{dt} = \mathbf{D}\Phi^{-1}\mathbf{X} + \Phi^{-1}\mathbf{B} \quad (2.16)$$

$$\frac{d\mathbf{Y}}{dt} = \mathbf{D}\mathbf{Y} + \Phi^{-1}\mathbf{B} \quad (2.17)$$

$$(2.18)$$

Defining $\mathbf{Y} = \begin{pmatrix} T_1 \\ T_2 \end{pmatrix}$, we have

$$\frac{d}{dt} \begin{pmatrix} T_1 \\ T_2 \end{pmatrix} = \begin{bmatrix} -\frac{1}{\tau_1} & 0 \\ 0 & -\frac{1}{\tau_2} \end{bmatrix} \begin{pmatrix} T_1 \\ T_2 \end{pmatrix} + \frac{1}{\phi_2 - \phi_1} \begin{bmatrix} \phi_2 & -1 \\ -\phi_1 & 1 \end{bmatrix} \begin{pmatrix} F \\ 0 \end{pmatrix} \quad (2.19)$$

or,

$$\frac{dT_1}{dt} = \frac{-T_1}{\tau_1} + \frac{\phi_2}{\phi_2 - \phi_1} \frac{F}{C} \quad (2.20)$$

$$\frac{dT_2}{dt} = \frac{-T_2}{\tau_2} - \frac{\phi_1}{\phi_2 - \phi_1} \frac{F}{C} \quad (2.21)$$

Re-writing, we have,

$$\frac{dT_1}{dt} = \frac{1}{\tau_1} \left(\frac{\tau_1\phi_2}{\phi_2 - \phi_1} \frac{F}{C} - T_1 \right) \quad (2.22)$$

$$\frac{dT_2}{dt} = \frac{1}{\tau_2} \left(\frac{-\tau_2\phi_1}{\phi_2 - \phi_1} \frac{F}{C} - T_2 \right) \quad (2.23)$$

We can compare this to the notation of [Millar et al., 2017](#) and see that

$$d_1 = \tau_1 \quad (2.24)$$

$$d_2 = \tau_2 \quad (2.25)$$

$$q_1 = \frac{\tau_1\phi_2}{C(\phi_2 - \phi_1)} \quad (2.26)$$

$$q_2 = -\frac{\tau_2\phi_1}{C(\phi_2 - \phi_1)} \quad (2.27)$$

$$(2.28)$$

Hence we have redemonstrated the equivalence of the two-layer model and a two-timescale impulse response model. Given the parameters of the two-layer model, we can now trivially derive the equivalent parameters of the two-timescale model. Doing the reverse is possible, but requires some more work in order to make a useable route drop out.

The first step is to follow [Geoffroy et al., 2013, Part 1](#), and define two extra constants

$$a_1 = \frac{\phi_2 \tau_1}{C(\phi_2 - \phi_1)} \lambda_0 \quad (2.29)$$

$$a_2 = -\frac{\phi_1 \tau_2}{C(\phi_2 - \phi_1)} \lambda_0 \quad (2.30)$$

$$(2.31)$$

These constants have the useful property that $a_1 + a_2 = 1$ (proof in Appendix A).

From above, we also see that

$$a_1 = \lambda_0 q_1 \quad (2.32)$$

$$a_2 = \lambda_0 q_2 \quad (2.33)$$

$$(2.34)$$

Hence

$$a_1 + a_2 = \lambda_0 q_1 + \lambda_0 q_2 = 1 \quad (2.35)$$

$$\lambda_0 = \frac{1}{q_1 + q_2} \quad (2.36)$$

Next we calculate C via

$$\frac{q_1}{d_1} + \frac{q_2}{d_2} = \frac{\phi_2}{C(\phi_2 - \phi_1)} - \frac{\phi_1}{C(\phi_2 - \phi_1)} = \frac{1}{C} \quad (2.37)$$

$$C = \frac{d_1 d_2}{q_1 d_2 + q_2 d_1} \quad (2.38)$$

We then use further relationships from Table 1 of [Geoffroy et al., 2013, Part 1](#) (proof is left to the reader) to calculate the rest of the constants.

Firstly,

$$\tau_1 a_1 + \tau_2 a_2 = \frac{C + \epsilon C_D}{\lambda_0} \quad (2.39)$$

$$\epsilon C_D = \lambda_0 (\tau_1 a_1 + \tau_2 a_2) - C \quad (2.40)$$

and then finally,

$$\tau_1 a_1 + \tau_2 a_2 = \frac{C + \epsilon C_D}{\lambda_0} \quad (2.41)$$

$$\epsilon \eta = \frac{\epsilon C_D}{\tau_1 a_2 + \tau_2 a_1} \quad (2.42)$$

The final thing to notice here is that C_D , ϵ and η are not uniquely-defined. This makes sense, as shown by [Geoffroy et al., 2013, Part 2](#), the introduction of the efficacy factor does not alter the behaviour of the system (it is still the same mathematical system) and so it is impossible for simply the two-timescale temperature response to uniquely define all three of these quantities. It can only define the products ϵC_D and $\epsilon \eta$. Hence when translating from the two-timescale model to the two-layer model with efficacy, an explicit choice for the efficacy must be made. This does not alter the temperature response but it does alter the implied ocean heat uptake of the two-timescale model.

Long story short, when deriving two-layer model parameters from a two-timescale model, one must specify the efficacy.

Given that $\mathbf{Y} = \Phi^{-1} \mathbf{X}$ i.e. $\mathbf{X} = \Phi \mathbf{Y}$, we can also relate the impulse response boxes to the

two layers. Finally, the equivalent of the two-timescale and two-layer models al-

$$\begin{pmatrix} T \\ T_D \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ \phi_1 & \phi_2 \end{pmatrix} \begin{pmatrix} T_1 \\ T_2 \end{pmatrix}$$

Finally, the equivalent of the two-timescale and two-layer models al-

lows us to also calculate the heat uptake of a two-timescale impulse response model. It is given by

$$\begin{aligned}\text{Heat uptake} &= C \frac{dT}{dt} + C_D \frac{dT_D}{dt} \\ &= F - \lambda_0 T + (1 - \epsilon)\eta(T - T_D) \\ &= F - \lambda_0(T_1 + T_2) + (1 - \epsilon)\eta((1 - \phi_1)T_1 + (1 - \phi_2)T_2) \\ &= F - \lambda_0(T_1 + T_2) - \eta(\epsilon - 1)((1 - \phi_1)T_1 + (1 - \phi_2)T_2)\end{aligned}$$

Running the code

Here we actually run the two implementations to explore their similarity.

```
[1]: import datetime as dt

import numpy as np
import pandas as pd
from openscm_units import unit_registry as ur
from scmdata.run import ScmRun, run_append

from openscm_twolayermodel import ImpulseResponseModel, TwoLayerModel

import matplotlib.pyplot as plt

/home/docs/checkouts/readthedocs.org/user_builds/openscm-two-layer-model/envs/latest/lib/
→python3.7/site-packages/openscm_twolayermodel/base.py:10: TqdmExperimentalWarning: →
→Using `tqdm.autonotebook.tqdm` in notebook mode. Use `tqdm.tqdm` instead to force →
→console mode (e.g. in jupyter console)
    import tqdm.autonotebook as tqdman
```

First we define a scenario to run.

```
[2]: time = np.arange(1750, 2501)
forcing = 0.05 * np.sin(time / 15 * 2 * np.pi) + 3.0 * time / time.max()

inp = ScmRun(
    data=forcing,
    index=time,
    columns={
        "scenario": "test_scenario",
        "model": "unspecified",
        "climate_model": "junk input",
        "variable": "Effective Radiative Forcing",
        "unit": "W/m^2",
        "region": "World",
    },
)
inp
```

[2]: <scmdata.ScmRun (timeseries: 1, timepoints: 751)>

Time:

- Start: 1750-01-01T00:00:00
- End: 2500-01-01T00:00:00

Meta:

climate_model	model	region	scenario	unit	\
---------------	-------	--------	----------	------	---

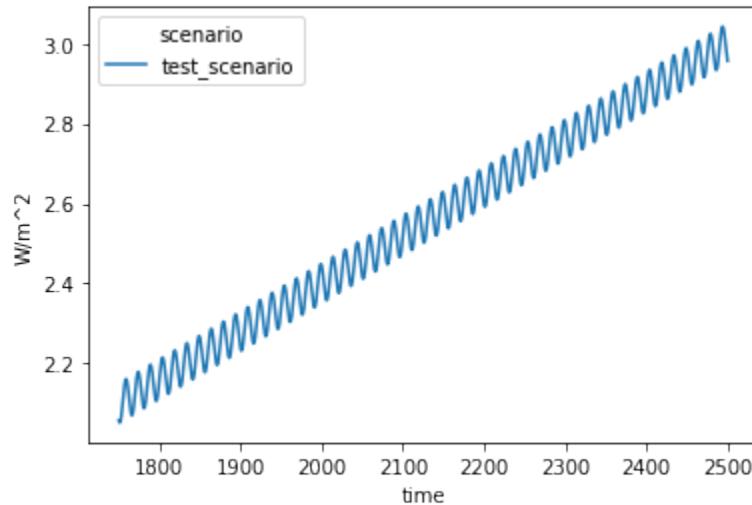

(continues on next page)

(continued from previous page)

```
0      junk input  unspecified  World  test_scenario  W/m^2
                                variable
0  Effective Radiative Forcing
```

[3]: # NBVAL_IGNORE_OUTPUT
inp.lineplot()

[3]: <AxesSubplot:xlabel='time', ylabel='W/m^2'>

Next we run the two-layer model. In order for it to be convertible to a two-timescale model, we must turn state-dependence off ($a=0$).

[4]: two_layer_config = {
 "du": 55 * ur("m"),
 "efficacy": 1.2 * ur("dimensionless"),
 # "efficacy": 1.0 * ur("dimensionless"),
 "a": 0 * ur("W/m^2/delta_degC^2"),
}

[5]: # NBVAL_IGNORE_OUTPUT
twolayer = TwoLayerModel(**two_layer_config)
res_twolayer = twolayer.run_scenarios(inp)
res_twolayer

```

Appendix A

We begin with the definitions of the a constants,

$$a_1 = \frac{\phi_2 \tau_1}{C(\phi_2 - \phi_1)} \lambda_0 \quad (2.43)$$

$$a_2 = -\frac{\phi_1 \tau_2}{C(\phi_2 - \phi_1)} \lambda_0 \quad (2.44)$$

$$(2.45)$$

We then have

$$a_1 + a_2 = \frac{\phi_2 \tau_1}{C(\phi_2 - \phi_1)} \lambda_0 - \frac{\phi_1 \tau_2}{C(\phi_2 - \phi_1)} \lambda_0 \quad (2.46)$$

$$= \frac{\lambda_0}{C(\phi_2 - \phi_1)} (\phi_2 \tau_1 - \phi_1 \tau_2) \quad (2.47)$$

Recalling the definition of the ϕ parameters,

$$\phi_1 = \frac{C}{2\epsilon\eta} (b^* - \sqrt{\delta}) \quad (2.48)$$

$$\phi_2 = \frac{C}{2\epsilon\eta} (b^* + \sqrt{\delta}) \quad (2.49)$$

We have,

$$\phi_2 - \phi_1 = \frac{C\sqrt{\delta}}{\epsilon\eta} \quad (2.50)$$

Recalling the definition of the τ parameters,

$$\tau_1 = \frac{CC_D}{2\lambda_0\eta}(b - \sqrt{\delta}) \quad (2.51)$$

$$\tau_2 = \frac{CC_D}{2\lambda_0\eta}(b + \sqrt{\delta}) \quad (2.52)$$

We have,

$$\phi_2\tau_1 - \phi_1\tau_2 = \frac{C}{2\epsilon\eta}(b^* + \sqrt{\delta}) \times \frac{CC_D}{2\lambda_0\eta}(b - \sqrt{\delta}) - \frac{C}{2\epsilon\eta}(b^* - \sqrt{\delta}) \times \frac{CC_D}{2\lambda_0\eta}(b + \sqrt{\delta}) \quad (2.53)$$

$$= \frac{C^2 C_d}{4\epsilon\eta^2\lambda_0} [(b^* + \sqrt{\delta})(b - \sqrt{\delta}) - (b^* - \sqrt{\delta})(b + \sqrt{\delta})] \quad (2.54)$$

$$= \frac{C^2 C_d}{4\epsilon\eta^2\lambda_0} [b^*b + b\sqrt{\delta} - b^*\sqrt{\delta} - \delta - bb^* + b\sqrt{\delta} - b^*\sqrt{\delta} + \delta] \quad (2.55)$$

$$= \frac{C^2 C_d}{2\epsilon\eta^2\lambda_0} [b\sqrt{\delta} - b^*\sqrt{\delta}] \quad (2.56)$$

$$= \frac{C^2 C_d \sqrt{\delta}}{2\epsilon\eta^2\lambda_0} [b - b^*] \quad (2.57)$$

Recalling the definition of the b parameters,

$$b = \frac{\lambda_0 + \epsilon\eta}{C} + \frac{\eta}{C_D} \quad (2.58)$$

$$b^* = \frac{\lambda_0 + \epsilon\eta}{C} - \frac{\eta}{C_D} \quad (2.59)$$

We then have

$$\phi_2\tau_1 - \phi_1\tau_2 = \frac{C^2 C_d \sqrt{\delta}}{2\epsilon\eta^2\lambda_0} \left[\frac{2\eta}{C_D} \right] \quad (2.60)$$

$$= \frac{C^2 \sqrt{\delta}}{\epsilon\eta\lambda_0} \quad (2.61)$$

Putting it all back together,

$$a_1 + a_2 = \frac{\lambda_0}{C(\phi_2 - \phi_1)} (\phi_2\tau_1 - \phi_1\tau_2) \quad (2.62)$$

$$= \frac{\lambda_0}{C} \frac{\epsilon\eta}{C\sqrt{\delta}} \frac{C^2 \sqrt{\delta}}{\epsilon\eta\lambda_0} \quad (2.63)$$

$$= 1 \quad (2.64)$$

2.2.2 One layer model

Here we show how to run our two-layer model as a single-layer model. There are two different ways to do this, which we present below.

Imports and loading data

```
[1]: # NBVAL_IGNORE_OUTPUT
import os.path

import numpy as np
import pandas as pd
from openscm_units import unit_registry as ur
import tqdm.autonotebook as tqdm
from scmdata import ScmRun, run_append

from openscm_twolayermodel import TwoLayerModel

import matplotlib.pyplot as plt

/home/docs/checkouts/readthedocs.org/user_builds/openscm-two-layer-model/envs/latest/lib/
→python3.7/site-packages/ipykernel_launcher.py:7: TqdmExperimentalWarning: Using `tqdm.
→autonotebook.tqdm` in notebook mode. Use `tqdm.tqdm` instead to force console mode (e.
→g. in jupyter console)
import sys
```

For this we use an idealised scenario which is a reasonable representation of the forcing which occurs in response to an abrupt doubling in atmospheric CO₂ concentrations (often referred to as an abrupt-2xCO₂ experiment).

```
[2]: run_length = 2000

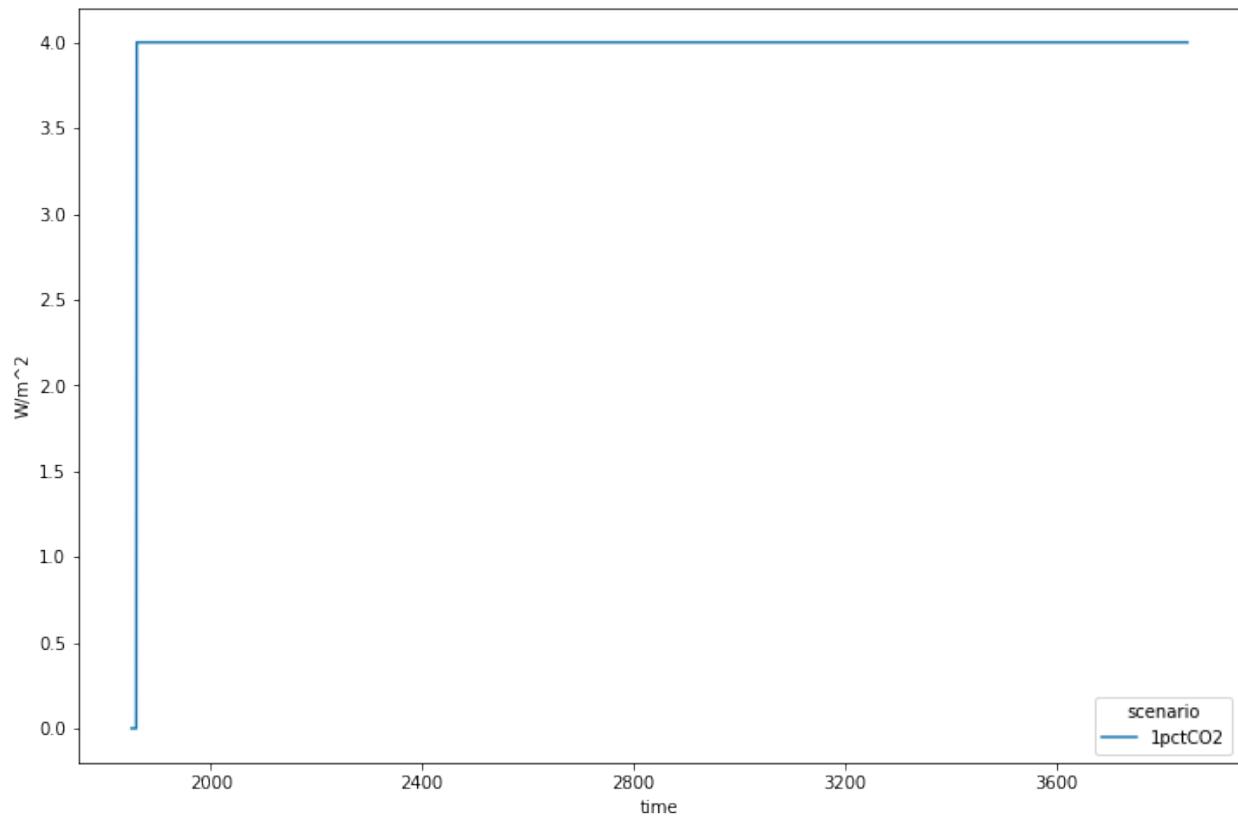

data = np.zeros(run_length)
data[10 : ] = 4.0

driver = ScmRun(
    data=data,
    index=1850 + np.arange(run_length),
    columns={
        "unit": "W/m^2",
        "model": "idealised",
        "scenario": "1pctCO2",
        "region": "World",
        "variable": "Effective Radiative Forcing",
    },
)
driver

[2]: <scmdata.ScmRun (timeseries: 1, timepoints: 2000)>
Time:
    Start: 1850-01-01T00:00:00
    End: 3849-01-01T00:00:00
Meta:
            model  region  scenario      unit                  variable
    0  idealised   World    1pctCO2  W/m^2  Effective Radiative Forcing
```

```
[3]: # NBVAL_IGNORE_OUTPUT
fig = plt.figure(figsize=(12, 8))
ax = fig.add_subplot(111)
driver.filter(variable="Effective Radiative Forcing").lineplot()
```

[3]: <AxesSubplot:xlabel='time', ylabel='W/m^2'>

No second layer

The first, and arguably the simplest way, to make a single layer model is to simply remove the connection between the top and second layers. Recalling the equations which define the two-layer model below,

$$C \frac{dT}{dt} = F - (\lambda_0 - aT)T - \epsilon\eta(T - T_D) \quad (2.65)$$

$$C_D \frac{dT_D}{dt} = \eta(T - T_D) \quad (2.66)$$

We see that we can effectively remove the second layer by setting $\eta = 0$.

[4]: TwoLayerModel().eta

[4]: 0.8 $\frac{\text{watt}}{(\text{delta_degree_Celsius}\cdot\text{meter}^2)}$

[5]: # NBVAL_IGNORE_OUTPUT
eta_values = np.array([0, 0.8]) * ur("W/m^2/K")

```

As we can see in the plots below, the runs with $\eta = 0$ only have a single timescale in their response. In contrast, the runs with $\eta \neq 0$ have two clear, distinct timescales. Notably, because equilibrium warming is independent of ocean heat uptake, the equilibrium warming is the same in all cases.

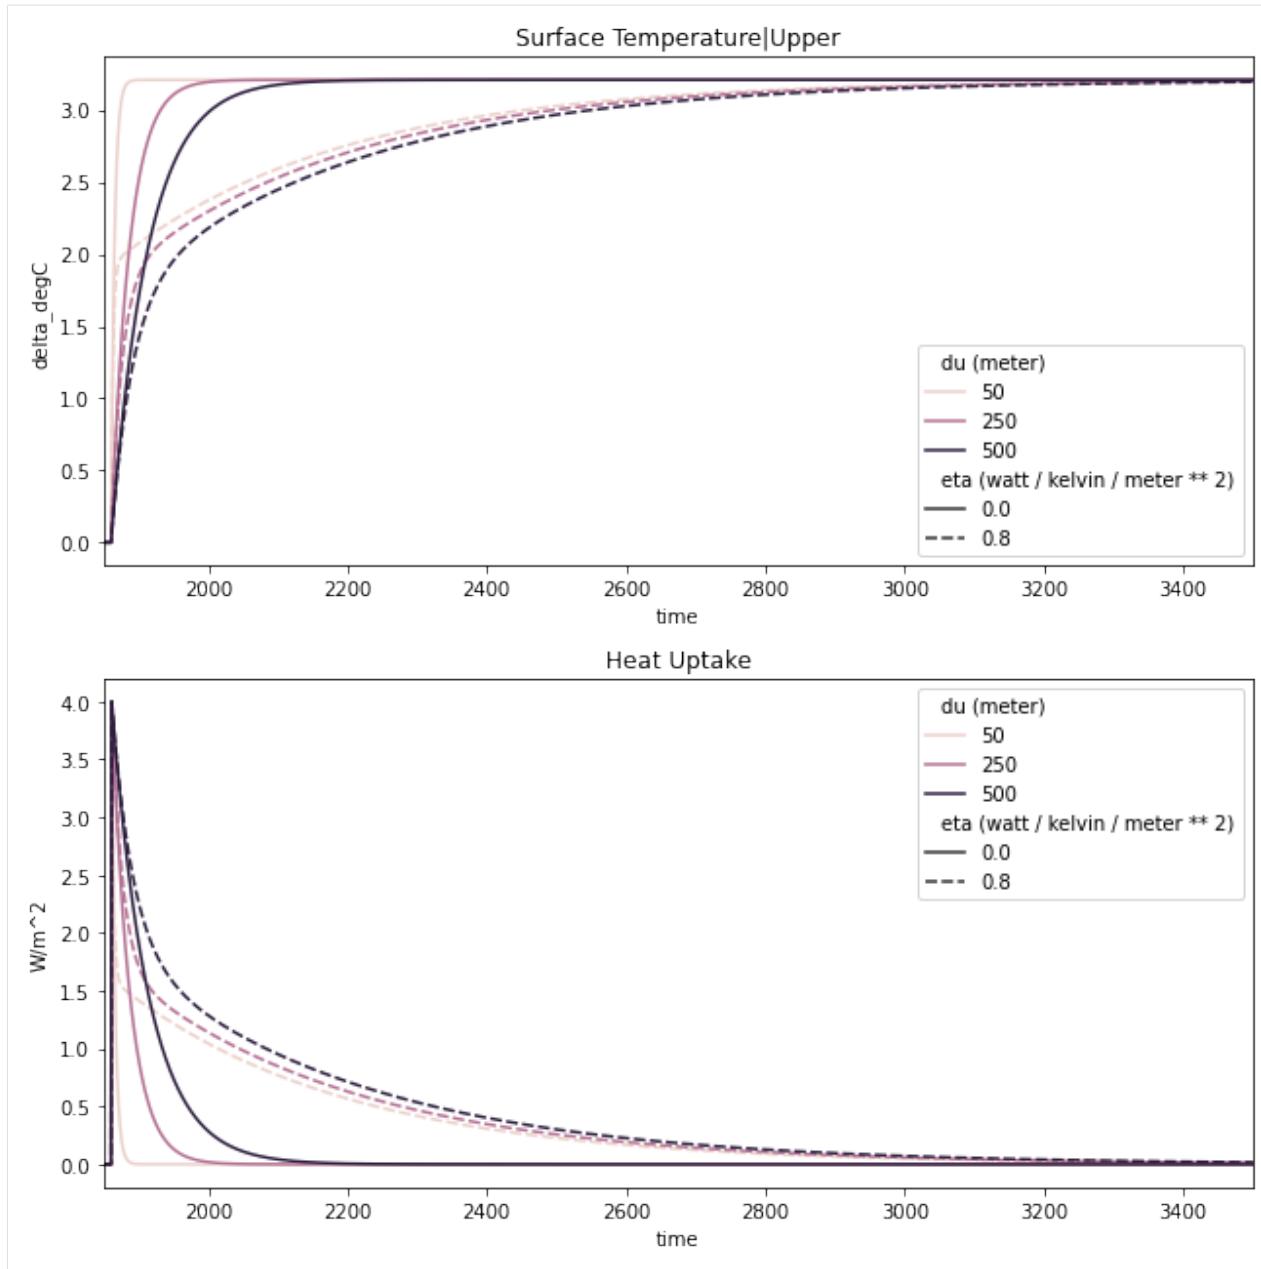

As expected, we see that the depth of the mixed-layer affects the response time of the mixed-layer (the only response time in the case of $\eta = 0$) whilst having a much smaller effect on the response time of the deep ocean.

```

Infinite reservoir second layer

If we make the deep ocean component of the two-layer model infinitely deep, then we also have a single layer model. The concept is described by Equation 4 of [Geoffroy et al. 2013, Part 1](#).

$$C \frac{dT}{dt} = F - (\lambda_0 - aT)T - \epsilon\eta(T - T_D) \quad (2.67)$$

$$C_D \frac{dT_D}{dt} = \eta(T - T_D) \quad (2.68)$$

In short, if $C_D \rightarrow \infty$, then $T_D = 0$ and the equation governing the mixed layer response becomes

$$C \frac{dT}{dt} = F - (\lambda_0 - aT)T - \epsilon\eta T \quad (2.69)$$

In effect, we alter the climate feedback factor from $\lambda_0 - aT$ to $\lambda_0 - aT + \epsilon\eta$ we increase the climate feedback factor and hence lower the equilibrium climate sensitivity.

```

As we can see below, as the deep ocean becomes deeper and deeper, its equivalent timescale increases. This demonstrates that the deep ocean is becoming increasingly close to being an infinite reservoir.

```
[11]: for v in equivalent_parameters:
    v[1]["d1"] = v[1]["d1"].to("yr")
    v[1]["d2"] = v[1]["d2"].to("yr")

equivalent_parameters

```

As shown in the plots below, as the deep ocean becomes bigger, it can uptake more heat and hence mixed-layer warming is reduced. However, whilst the deep ocean is finite, the mixed-layer warming does eventually reach the same equilibrium (independent of deep ocean depth), it just takes longer to do so. Once the deep ocean becomes infinite, as discussed above, we effectively have a single-layer model with an increased climate feedback factor (lower equilibrium climate sensitivity) which can uptake heat forever.

DEVELOPMENT

If you're interested in contributing to OpenSCM Two Layer Model, we'd love to have you on board! This section of the docs details how to get setup to contribute and how best to communicate.

- *Contributing*
- *Getting setup*
 - *Getting help*
 - * *Development tools*
 - * *Other tools*
- *Formatting*
- *Buiding the docs*
 - *Gotchas*
 - *Docstring style*
- *Releasing*
 - *First step*
 - *Push to repository*
- *Why is there a Makefile in a pure Python repository?*

3.1 Contributing

All contributions are welcome, some possible suggestions include:

- tutorials (or support questions which, once solved, result in a new tutorial :D)
- blog posts
- improving the documentation
- bug reports
- feature requests
- pull requests

Please report issues or discuss feature requests in the [OpenSCM Two Layer Model issue tracker](#). If your issue is a feature request or a bug, please use the templates available, otherwise, simply open a normal issue.

As a contributor, please follow a couple of conventions:

- Create issues in the [OpenSCM Two Layer Model issue tracker](#) for changes and enhancements, this ensures that everyone in the community has a chance to comment
- Be welcoming to newcomers and encourage diverse new contributors from all backgrounds: see the [Python Community Code of Conduct](#)
- Only push to your own branches, this allows people to force push to their own branches as they need without fear or causing others headaches
- Start all pull requests as draft pull requests and only mark them as ready for review once they've been rebased onto master, this makes it much simpler for reviewers
- Try and make lots of small pull requests, this makes it easier for reviewers and faster for everyone as review time grows exponentially with the number of lines in a pull request

3.2 Getting setup

To get setup as a developer, we recommend the following steps (if any of these tools are unfamiliar, please see the resources we recommend in [Development tools](#)):

1. Install conda and make
2. Run `make virtual-environment`, if that fails you can try doing it manually
 1. Change your current directory to OpenSCM Two Layer Model's root directory (i.e. the one which contains `README.rst`), `cd openscm-twolayermodel`
 2. Create a virtual environment to use with OpenSCM Two Layer Model `python3 -m venv venv`
 3. Activate your virtual environment `source ./venv/bin/activate`
 4. Upgrade pip `pip install --upgrade pip`
 5. Install the development dependencies (very important, make sure your virtual environment is active before doing this) `pip install -e .[dev]`
3. Make sure the tests pass by running `make checks`, if that fails the commands can be read out of the `Makefile`

3.2.1 Getting help

Whilst developing, unexpected things can go wrong (that's why it's called 'developing', if we knew what we were doing, it would already be 'developed'). Normally, the fastest way to solve an issue is to contact us via the [issue tracker](#). The other option is to debug yourself. For this purpose, we provide a list of the tools we use during our development as starting points for your search to find what has gone wrong.

Development tools

This list of development tools is what we rely on to develop OpenSCM Two Layer Model reliably and reproducibly. It gives you a few starting points in case things do go inexplicably wrong and you want to work out why. We include links with each of these tools to starting points that we think are useful, in case you want to learn more.

- [Git](#)
- [Make](#)
- [Conda virtual environments](#)

- Pip and pip virtual environments
- Tests
 - we use a blend of `pytest` and the inbuilt Python testing capabilities for our tests so checkout what we've already done in `tests` to get a feel for how it works
- Continuous integration (CI) (also [brief intro blog post](#) and a longer read)
 - we use GitHub CI for our CI but there are a number of good providers
- Jupyter Notebooks
 - Jupyter is automatically included in your virtual environment if you follow our [*Getting setup*](#) instructions
- Sphinx

Other tools

We also use some other tools which aren't necessarily the most familiar. Here we provide a list of these along with useful resources.

- Regular expressions
 - we use regex101.com to help us write and check our regular expressions, make sure the language is set to Python to make your life easy!

3.3 Formatting

To help us focus on what the code does, not how it looks, we use a couple of automatic formatting tools. These automatically format the code for us and tell us where the errors are. To use them, after setting yourself up (see [*Getting setup*](#)), simply run `make format`. Note that `make format` can only be run if you have committed all your work i.e. your working directory is 'clean'. This restriction is made to ensure that you don't format code without being able to undo it, just in case something goes wrong.

3.4 Building the docs

After setting yourself up (see [*Getting setup*](#)), building the docs is as simple as running `make docs` (note, run `make -B docs` to force the docs to rebuild and ignore `make` when it says '... index.html is up to date'). This will build the docs for you. You can preview them by opening `docs/build/html/index.html` in a browser.

For documentation we use [Sphinx](#). To get ourselves started with Sphinx, we started with [this example](#) then used Sphinx's [getting started guide](#).

3.4.1 Gotchas

To get Sphinx to generate pdfs (rarely worth the hassle), you require [Latexmk](#). On a Mac this can be installed with `sudo tlmgr install latexmk`. You will most likely also need to install some other packages (if you don't have the full distribution). You can check which package contains any missing files with `tlmgr search --global --file [filename]`. You can then install the packages with `sudo tlmgr install [package]`.

3.4.2 Docstring style

For our docstrings we use numpy style docstrings. For more information on these, [here](#) is the full guide and the quick reference we also use.

3.5 Releasing

3.5.1 First step

1. Test installation with dependencies `make test-install`
2. Update `CHANGELOG.rst`
 - add a header for the new version between `master` and the latest bullet point
 - this should leave the section underneath the master header empty
3. `git add .`
4. `git commit -m "Prepare for release of vX.Y.Z"`
5. `git tag vX.Y.Z`
6. Test version updated as intended with `make test-install`

3.5.2 Push to repository

To do the release, push the tags and the repository state.

1. `git push`
2. `git push --tags`

Assuming all the checks pass, this automatically triggers a release on PyPI via the `.github/workflows/ci-cd-workflow.yml` action.

3.6 Why is there a Makefile in a pure Python repository?

Whilst it may not be standard practice, a `Makefile` is a simple way to automate general setup (environment setup in particular). Hence we have one here which basically acts as a notes file for how to do all those little jobs which we often forget e.g. setting up environments, running tests (and making sure we're in the right environment), building docs, setting up auxillary bits and pieces.

CHAPTER
FOUR

BASE API

Module containing the base for model implementations

class `openscm_twolayermodel.base.Model`

Bases: `abc.ABC`

Base class for model implementations

reset()

Reset everything so that a new run can be performed.

Called as late as possible before `run()`.

run()

Run the model.

abstract set_drivers(*args, **kwargs)

Set the model's drivers

step()

Do a single time step.

class `openscm_twolayermodel.base.TwoLayerVariant`

Bases: `openscm_twolayermodel.base.Model`

Base for variations of implementations of the two-layer model

property delta_t

`pint.Quantity` Time step for forward-differencing approximation

property erf

`pint.Quantity` Effective radiative forcing

reset()

Reset everything so that a new run can be performed.

Called as late as possible before `run()`.

run()

Run the model.

run_scenarios(scenarios, driver_var='Effective Radiative Forcing', progress=True)

Run scenarios.

The model timestep is automatically adjusted based on the timestep used in `scenarios`. The timestep used in `scenarios` must be constant because this implementation has a constant timestep. Pull requests to upgrade the implementation to support variable timesteps are welcome <https://github.com/openscm/openscm-twolayermodel/pulls>.

Parameters

- **scenarios** (`ScmDataFrame` or `ScmRun` or `pyam.IamDataFrame` or `pd.DataFrame` or `np.ndarray` or `str`) – Scenarios to run. The input will be converted to an `ScmRun` before the run takes place.

- **driver_var** (`str`) – The variable in `scenarios` to use as the driver of the model
- **progress** (`bool`) – Whether to display a progress bar

Returns Results of the run (including drivers)

Return type `ScmRun`

Raises `ValueError` – No data is available for `driver_var` in the "World" region in `scenarios`.

`set_drivers(erf)`

Set drivers for a model run

Parameters `erf` (`pint.Quantity`) – Effective radiative forcing (W/m²) to use to drive the model

Raises `AssertionError` – `erf` is not one-dimensional

`step()`

Do a single time step.

CHAPTER
FIVE

IMPULSE RESPONSE MODEL API

Module containing the impulse response model

The 2-timescale impulse response model is mathematically equivalent to the two-layer model without state dependence.

```
class openscm_twolayermodel.impulse_response_model.ImpulseResponseModel(q1=<Quantity(0.3,  
    'delta_degree_Celsius  
    * meter ** 2 / watt')>,  
    q2=<Quantity(0.4,  
    'delta_degree_Celsius  
    * meter ** 2 / watt')>,  
    d1=<Quantity(9.0,  
    'a')>,  
    d2=<Quantity(400.0,  
    'a')>, effi-  
    cacy=<Quantity(1.0,  
    'dimensionless')>,  
    delta_t=<Quantity(0.08333333333333333,  
    'a')>)
```

Bases: *openscm_twolayermodel.base.TwoLayerVariant*

TODO: top line and paper references

This implementation uses a forward-differencing approach. This means that temperature and ocean heat uptake values are start of timestep values. For example, temperature[i] is only affected by drivers from the i-1 timestep. In practice, this means that the first temperature and ocean heat uptake values will always be zero and the last value in the input drivers has no effect on model output.

```
property d1  
    pint.Quantity Response timescale of first box  
  
property d2  
    pint.Quantity Response timescale of second box  
  
property delta_t  
    pint.Quantity Time step for forward-differencing approximation  
  
property efficacy  
    pint.Quantity Efficacy factor  
  
property erf  
    pint.Quantity Effective radiative forcing  
  
get_two_layer_parameters()  
    Get equivalent two-layer model parameters
```

For details on how the equivalence is calculated, please see the notebook `impulse-response-equivalence.ipynb` in the OpenSCM Two Layer model repository.

Returns `dict of str` – Input arguments to initialise an `openscm_twolayermodel.TwoLayerModel` with the same temperature response as `self`

Return type `pint.Quantity`

property `q1`

`pint.Quantity` Sensitivity of first box response to radiative forcing

property `q2`

`pint.Quantity` Sensitivity of second box response to radiative forcing

reset()

Reset everything so that a new run can be performed.

Called as late as possible before `run()`.

run()

Run the model.

run_scenarios(`scenarios, driver_var='Effective Radiative Forcing', progress=True`)

Run scenarios.

The model timestep is automatically adjusted based on the timestep used in `scenarios`. The timestep used in `scenarios` must be constant because this implementation has a constant timestep. Pull requests to upgrade the implementation to support variable timesteps are welcome <https://github.com/openscm/openscm-twolayermodel/pulls>.

Parameters

- **scenarios** (`ScmDataFrame` or `ScmRun` or `pyam.IamDataFrame` or `pd.DataFrame` or `np.ndarray` or `str`) – Scenarios to run. The input will be converted to an `ScmRun` before the run takes place.
- **driver_var** (`str`) – The variable in `scenarios` to use as the driver of the model
- **progress** (`bool`) – Whether to display a progress bar

Returns Results of the run (including drivers)

Return type `ScmRun`

Raises `ValueError` – No data is available for `driver_var` in the "World" region in `scenarios`.

set_drivers(`erf`)

Set drivers for a model run

Parameters `erf` (`pint.Quantity`) – Effective radiative forcing (W/m^2) to use to drive the model

Raises `AssertionError` – `erf` is not one-dimensional

step()

Do a single time step.

TWO LAYER MODEL API

Module containing the two-layer model

```
class openscm_twolayermodel.two_layer_model.TwoLayerModel(du=<Quantity(50, 'meter')>,
                                                          dl=<Quantity(1200, 'meter')>,
                                                          lambda0=<Quantity(1.24666667, 'watt /
                                                          delta_degree_Celsius / meter ** 2')>,
                                                          a=<Quantity(0.0, 'watt /
                                                          delta_degree_Celsius ** 2 / meter ** 2')>, efficacy=<Quantity(1.0,
                                                          'dimensionless')>, eta=<Quantity(0.8,
                                                          'watt / delta_degree_Celsius / meter ** 2')>, delta_t=<Quantity(31557600.0,
                                                          'second')>)
```

Bases: *openscm_twolayermodel.base.TwoLayerVariant*

TODO: top line and paper references

This implementation uses a forward-differencing approach. This means that temperature and ocean heat uptake values are start of timestep values. For example, temperature[i] is only affected by drivers from the i-1 timestep. In practice, this means that the first temperature and ocean heat uptake values will always be zero and the last value in the input drivers has no effect on model output.

```
property a
    pint.Quantity Dependence of climate feedback factor on temperature

property delta_t
    pint.Quantity Time step for forward-differencing approximation

property dl
    pint.Quantity Depth of lower layer

property du
    pint.Quantity Depth of upper layer

property efficacy
    pint.Quantity Efficacy factor

property erf
    pint.Quantity Effective radiative forcing

property eta
    pint.Quantity Heat transport efficiency

get_impulse_response_parameters()
    Get equivalent two-timescale impulse response model parameters
```

For details on how the equivalence is calculated, please see the notebook `impulse-response-equivalence.ipynb` in the OpenSCM Two Layer model repository.

Returns `dict of str` – Input arguments to initialise an `openscm_twolayermodel.ImpulseResponseModel` with the same temperature response as `self`

Return type `pint.Quantity`

Raises `ValueError` – `self.a` is non-zero, the two-timescale model does not support state-dependence.

property heat_capacity_lower

`pint.Quantity` Heat capacity of lower layer

property heat_capacity_upper

`pint.Quantity` Heat capacity of upper layer

property lambda0

`pint.Quantity` Initial climate feedback factor

reset()

Reset everything so that a new run can be performed.

Called as late as possible before `run()`.

run()

Run the model.

run_scenarios(`scenarios, driver_var='Effective Radiative Forcing', progress=True`)

Run scenarios.

The model timestep is automatically adjusted based on the timestep used in `scenarios`. The timestep used in `scenarios` must be constant because this implementation has a constant timestep. Pull requests to upgrade the implementation to support variable timesteps are welcome <https://github.com/openscm/openscm-twolayermodel/pulls>.

Parameters

- **scenarios** (`ScmDataFrame` or `ScmRun` or `pyam.IamDataFrame` or `pd.DataFrame` or `np.ndarray` or `str`) – Scenarios to run. The input will be converted to an `ScmRun` before the run takes place.
- **driver_var** (`str`) – The variable in `scenarios` to use as the driver of the model
- **progress** (`bool`) – Whether to display a progress bar

Returns Results of the run (including drivers)

Return type `ScmRun`

Raises `ValueError` – No data is available for `driver_var` in the "World" region in `scenarios`.

set_drivers(`erf`)

Set drivers for a model run

Parameters `erf` (`pint.Quantity`) – Effective radiative forcing (W/m^2) to use to drive the model

Raises `AssertionError` – `erf` is not one-dimensional

step()

Do a single time step.

CHAPTER
SEVEN

CONSTANTS API

Physical constants used in calculations

```
openscm_twolayermodel.constants.DENSITY_WATER = <Quantity(1000.0, 'kilogram / meter **  
3')>  
density of water
```

Type pint.Quantity

```
openscm_twolayermodel.constants.HEAT_CAPACITY_WATER = <Quantity(4181.0, 'joule /  
delta_degree_Celsius / kilogram')>  
heat capacity of water
```

Type pint.Quantity

CHAPTER
EIGHT

ERRORS API

Exceptions raised within `openscm_twolayermodel`

exception `openscm_twolayermodel.errors.ModelStateError`

Bases: `ValueError`

Exception raised if a model's state is incompatible with the action

args

with_traceback()

`Exception.with_traceback(tb)` – set `self.__traceback__` to `tb` and return `self`.

exception `openscm_twolayermodel.errors.UnitError`

Bases: `ValueError`

Exception raised if something has the wrong units

args

with_traceback()

`Exception.with_traceback(tb)` – set `self.__traceback__` to `tb` and return `self`.

CHAPTER
NINE

UTILS API

Utility functions

```
openscm_twolayermodel.utils.convert_lambda_to_ecs(lambda_val, f2x=<Quantity(3.74, 'watt / meter **  
2')>)
```

Convert a lambda value to equilibrium climate sensitivity (ECS)

Parameters

- **lambda_val** (pint.Quantity) – Value of lambda to convert to ECS
- **f2x** (pint.Quantity) – Value of the forcing due to a doubling of atmospheric CO₂ to assume during the conversion

Returns ECS value

Return type pint.Quantity

Raises [TypeError](#) – lambda_val or f2x is not a pint.Quantity.

CHANGELOG

All notable changes to this project will be documented in this file.

The format is based on [Keep a Changelog](#), and this project adheres to [Semantic Versioning](#).

The changes listed in this file are categorised as follows:

- Added: new features
- Changed: changes in existing functionality
- Deprecated: soon-to-be removed features
- Removed: now removed features
- Fixed: any bug fixes
- Security: in case of vulnerabilities.

10.1 v0.2.3 - 2021-04-27

10.1.1 Fixed

- (#34, #35, #36) Final tweaks to JOSS paper

10.2 v0.2.2 - 2021-04-27

10.2.1 Added

- (#33) Information in README and testing for conda install

10.2.2 Changed

- (#32) Include LICENSE, README.rst and CHANGELOG in package
- (#30) Require scmdata>=0.9
- (#27) Fixed the discussion (in the relevant notebook) of how a one-layer model can be made from the two-layer implementation here

10.2.3 Fixed

- (#30) Incorrect call to `scmdata.ScmRun()` in tests

10.3 v0.2.1 - 2020-12-23

10.3.1 Added

- (#20) Statement of need to the README following JOSS review (closes #18)

10.3.2 Changed

- (#26) Updated to new `scmdata` version (and hence new `openscm-units` API)
- (#25) JOSS paper following JOSS review 1
- (#23) Moved notebooks into full documentation following JOSS review (closes #17)
- (#21) Quoted pip install instructions to ensure cross-shell compatibility following JOSS review (closes #16)
- (#20) Option to remove `tqdm` progress bar by passing `progress=False`

10.4 v0.2.0 - 2020-10-09

10.4.1 Added

- (#7) JOSS paper draft

10.4.2 Changed

- (#7) Require `scmdata>=0.7`

10.5 v0.1.2 - 2020-31-07

10.5.1 Changed

- (#12) Upgrade to `scmdata>=0.6.2` so that package can be installed

10.6 v0.1.1 - 2020-06-29

10.6.1 Added

- (#8) Add notebook showing how to run a single-layer model

10.6.2 Changed

- (#11) Re-wrote the getting started notebook
- (#10) Re-wrote CHANGELOG
- (#9) Update to scmdata 0.5.Y

10.7 v0.1.0 - 2020-05-15

10.7.1 Added

- (#3) Add first implementation of the models
- (#1) Setup repository
